

10 Key Findings From a Rapidly Acidifying Arctic Ocean

—By Julia Whitty, Mother Jones Tue May. 7, 2013 <http://www.motherjones.com/blue-marble/2013/05/arctic-ocean-rapidly-getting-more-a>

As predicted by chemistry, change in the Arctic Ocean is accelerating as temperatures warm faster than the global average, as the sea ice melts, as northern rivers run straight into the atmosphere. The *Arctic Ocean Acidification Assessment*, a new report from the Arctic Monitoring and Assessment Program (AMAP), presents these 10 key findings.

1. Arctic marine waters are experiencing widespread and rapid ocean acidification. In the Nordic Seas, acidification is taking place over a wide range of ocean depths. Other ocean acidification signals have also been encountered in surface waters of the Bering Strait and the Canada Basin of the central Arctic Ocean.

2. The primary driver of ocean acidification is uptake of carbon dioxide emitted to the atmosphere by human activities. The ocean has swallowed our atmospheric carbon dioxide, and in the process, delaying even more warming has been the increasing acidification of seawater. The average acidity of surface ocean waters worldwide is now ~30% higher than at the pre-industrial level.

3. The Arctic Ocean is especially vulnerable to ocean acidification. Arctic rivers plus melting ice input huge (and increasing) amounts of freshwater into the Arctic Ocean. Add the fact that dramatic decreases in Arctic summer sea-ice cover—real and projected—allow for greater transfer of CO₂ from the atmosphere to the ocean.

4. Acidification is not uniform across the Arctic Ocean. Other processes influence the pace and extent of ocean acidification. Rivers, sea-floor sediments, and coastal upwellings influence local ocean acidification. Sea-ice cover, freshwater inputs, and plant growth and decay also influence local ocean acidification. The contributions of these processes vary from place to place, season to season.

5. Arctic marine ecosystems are highly likely to undergo significant change due to ocean acidification. Arctic marine ecosystems are generally characterized by low species diversity. The integrity of such a simple structure depends greatly on keystone species. Pteropods (sea butterflies) and echinoderms (sea stars, urchins) are key food-web organisms. Most biological studies have been undertaken in other ocean regions. Arctic-specific long-term studies are urgently needed.

6. Ocean acidification will have direct and indirect effects on arctic marine life. Some marine organisms will respond positively to new conditions associated with ocean acidification over the next centuries. While some seagrasses appear to thrive under such conditions. Birds and mammals are not likely to be directly affected by acidification but may be indirectly affected through changes in food web structure, which nutrients and essential trace elements in seawater are available to marine organisms. Shell-building Arctic mollusks are likely to be negatively affected by acidification.

and early larval stages may be more sensitive. In general, early life stages are more susceptible to direct effects of ocean acidification than later life stages.

7. Ocean acidification impacts must be assessed in the context of other changes happening in Arctic waters. Arctic marine organisms are experiencing not only direct effects of ocean acidification but also indirect effects through changes in food web interactions, predator and prey, or among competitors—also play an important role in shaping ocean communities. As different marine life responds to environmental change in different ways, the net effect is uncertain and will vary by region and species. The full extent of the impacts is not yet known.

8. Ocean acidification is one of several factors that may contribute to alteration of fish species' composition in the Arctic Ocean. Ocean acidification is likely to affect the composition of fish species in the Arctic Ocean. Arctic change includes rising temperatures, diminishing sea ice, and freshening surface waters.

9. Ocean acidification may affect Arctic fisheries. Few studies have estimated the socio-economic impacts of ocean acidification on fisheries, and most have focused on the potential for reduced yields of commercially important species. Some species may be more robust to ocean acidification, but the magnitude and direction of change are uncertain. Fish stocks may be more robust to ocean acidification if other stresses—for example, overfishing—also affect the fishery.

10. Ecosystem changes associated with ocean acidification may affect the livelihoods of Arctic peoples. Marine species harvested by northern coastal communities are likely to be affected by ocean acidification. While some species may be more robust to ocean acidification, others may be less so. Unaffected species, but these changes would likely exert a cultural toll. Recreational fish catches may change to different species. While marine mammals—important to many Arctic communities—are not directly affected by ocean acidification, changes in their prey may affect their health and survival.
